KINETIC STUDY OF RARE EARTH-EDTA-TIRON MIXED COMPLEX
FORMATION REACTION IN AQUEOUS SOLUTION

BY HIROSHI NAKATANI* AND JIRO OSUGI

Mixed complex formation reactions of the EDTA-rare earth complex with tiron were studied by the temperature jump method. The two step mechanism involving the intermediate complexes of EDTA-rare earth-protonated tiron ion agreed reasonably with the concentration dependency of observed relaxation times. The values of the formation rate constants were the order of $10^5 \text{ M}^{-1} \text{ sec}^{-1}$, which are two or three order less than the values in hydrated rare earth ions-murexide, -oxalic acid and -anthranic acid systems.

The ligand-ligand interaction, electrostatic and steric repulsion, acts as the retarding effects in these mixed complex formation reactions.

Introduction

Rare earth-EDTA complexes react with the second ligand such as tiron (4, 5-dihydroxybenzene-1, 3-disulfonic acid) and form mixed complexes¹⁾. From the study of stability constants of various mixed complexes, rare earth ions are considered to have coordination number larger than six^{1,2)}. Crystallographic studies indicate that the coordination number of rare earth ions is eight or nine³⁾. EDTA has six binding sites, while tiron has two. Therefore, in mixed complexes, the whole binding sites of two ligands may coordinate to the rare earth ion. The rate constants of complexation reactions of rare earth ions with murexide, oxalic acid and anthranic acid are very large ($10^7 \sim 10^8 \text{ M}^{-1} \text{ sec}^{-1}$)^{4,6)}. In the mixed complex formation reaction, ligand-ligand interactions, for example, steric hindrance and electrostatic repulsion, may influence the reaction rate. Using the temperature jump method, the rare earth-EDTA-tiron systems were treated kinetically in this investigation.

Experimental

The stock solutions of rare earth ions were prepared by adding oxides to known quantities of dilute

perchloric acid. The concentrations of rare earth ions in stock solutions were checked by the standard gravimetric method. The solutions containing the rare earth ion, EDTA, tiron and indicator (phenol red) were prepared and made up to ionic strength 0.1 with the concentrated sodium perchlorate solution. The rare earth ion and EDTA were always in the ratio 1 : 1. Therefore, in the sample solutions free EDTA ions and the rare earth ions uncoordinate with EDTA were negligible¹⁾.

The experimental procedures and instrumentation are described in a previous paper⁷⁾. A representative relaxation spectrum for the Dy^{3+} -EDTA-tiron-indicator solution is shown in Fig. 1. No relaxation was observed for Dy^{3+} -EDTA-indicator solutions. The relaxation was seen when Dy^{3+} -tiron-indicator solutions were used. But the direction of the relaxation signal was opposite to Fig. 1. This relaxation may be due to the complexation reactions between Dy^{3+} , DyOH^{2+} and tiron ions⁸⁾.

Fig. 1 Relaxation curve of EDTA- Dy^{3+} -tiron system at 25°C
 $(\text{EDTA})_0 = (\text{Dy}^{3+})_0 = 2.50 \times 10^{-3}\text{M}$, $(\text{tiron})_0 = 1.00 \times 10^{-3}\text{M}$,
 pH 7.65, indicator is phenol red
 The sweep rate is $200 \mu\text{sec/div}$.
 Vertical scale is arbitrary units of absorbance at 560 nm.

Results and Discussion

The initial concentrations of rare earth ions (and EDTA) and tiron, the pH values and the observed relaxation times, are shown in Table 1. Each relaxation time listed in Table 1 is an average of at least three photographic determinations. Dy^{3+} , Ho^{3+} , Er^{3+} , Yb^{3+} and Y^{3+} were used in this investigation. Gd^{3+} -EDTA-tiron-indicator solutions were tested but relaxation signals were too small to treat quantitatively (the relaxation times were in the range of $100 \mu\text{sec}$). No relaxation was observed when La^{3+} was used as the metal ion. If M^{3+} is the rare earth ions, and E^{4-} and T^{4-} are the completely dissociated forms of EDTA and tiron respectively, the ions contributing to relaxations in pH 7~8 are EM^{3-} , T^{4-} , HT^{3-} , H_2T^{2-} and EMT^{2-} ¹⁾.

Rare Earth-EDTA-Tiron Mixed Complex Formation Reaction

105

The following one-step reactions were considered to test the concentration dependency of relaxation times:

Table 1 Experimental conditions and relaxation times for rare earth ions-EDTA-tiron solutions

(M ³⁺) ₀	(EDTA) ₀ 10 ⁻³ M	(tiron) ₀ 10 ⁻³ M	pH	τ m sec
(Dy ³⁺) ₀	0.300	0.300	7.60	0.77
	0.500	0.500	7.60	0.57
	0.500	1.00	7.63	0.81
	0.800	0.800	7.70	0.55
	1.00	1.00	7.44	0.41
	2.00	1.00	7.68	0.36
	2.00	1.00	7.62	0.31
	2.50	1.00	7.65	0.29
(Ho ³⁺) ₀	0.500	0.500	7.58	1.02
	1.00	1.00	7.49	0.68

	3.00	3.00	7.48	1.2

(M³⁺)₀, (EDTA)₀, and (tiron)₀, represent the initial concentrations of the rare earth ion, EDTA and tiron, respectively.

Phenol red was used as indicator (initial concentration 1.5 × 10⁻⁵ M).

where k_1 , k_{-1} , k'_1 and k'_{-1} are the rate constants.

The relaxation time as a function of equilibrium concentrations was derived from reactions (1), (2) and acid-base equilibria of tiron and the indicator⁹). But the observed relaxation times did not fit to the derived equation. Next, the following two-step reaction was considered.

K_d is the proton dissociation constant of EMHT^{4-} . EMHT^{4-} in equation (3) is the intermediate ion which was not detected by the study of potentiometric titrations. But such an intermediate was treated in Ni^{2+} , Co^{2+} and Zn^{2+} -tiron systems by Kustin *et al.*¹⁰). It is possible that in the rare earth-EDTA-tiron systems EMHT^{4-} exists though the concentration may be very low compared with EMT^{5-} . To derive the relaxation time, the following protolytic reactions must be involved in the reaction mechanism.

where In^- represents the dissociated species of the indicator.

The reciprocal relaxation time is deduced by Eqs. (3)~(6) assuming protolytic reactions are very fast compared with the complexation reaction between EM^- and HT^{3-} . The result is

$$\frac{1}{\tau} = k_1 \cdot AA, \quad (7)$$

$$AA = (\text{EM}^-) \frac{\alpha}{(1 + \alpha)} + (\text{HT}^{3-}) + \frac{K_d}{(1 + \beta)K_m K_1}, \quad (8)$$

Fig. 2 Plot of $1/\tau$ vs. AA for Er^{3+}

Δ : $K_d = 10^{-7}$
 \circ : $K_d = 10^{-6}$
 \bullet : $K_d = 10^{-5}$

Fig. 3 Plot of $1/\tau$ vs. AA for Dy^{3+} , Ho^{3+} , Y^{3+} , Yb^{3+} at $K_d \geq 10^{-5}$

10) K. Kustin and K. O. Watkins, *Inorg. Chem.*, **3**, 1706 (1964)

$$\alpha = \frac{\delta(\text{EMT}^{5-})}{\delta(\text{EMHT}^{4-})}, \quad \beta = -\frac{\delta(\text{EM}^-)}{\delta(\text{HT}^{3-})},$$

$$K_m = \frac{(\text{EMT}^{5-})}{(\text{EM}^-)(\text{T}^{4-})}.$$

(EM^-), etc., are the equilibrium concentrations and δ shows the small deviation from the equilibrium concentration. α and β are calculated numerically using equilibrium concentrations and equilibrium constants. The values of K_1 , K_2 and K_m were used from literature values¹⁾. As the value of K_d was not known, the trial values of K_d were used and the numerical values of AA in Eq. (8) were calculated. If the reaction mechanism (3) and the value of K_d were suitable, the plot of $1/\tau$ vs. AA should be a straight line through the original point. The plot for Er^{3+} is shown in Fig. 2. It is clear that the plot is a straight line through the original point at $K_d \geq 10^{-5}$. The plot is nearly independent of the values of K_d over 10^{-5} . The concentrations of EMHT^{4-} are very low compared with those of EMT^{5-} within these values of K_d . The plot for Dy^{3+} , Ho^{3+} , Y^{3+} and Yb^{3+} at $K_d \geq 10^{-5}$ is shown in Fig. 3. The rate constant k_1 was obtained from the slope for each rare earth ion. The values of k_1 are listed in table 2.

Table 2 Rate constants of the complexation reaction of the type

$\text{EM}^- + \text{HT}^{3-} \xrightleftharpoons[k_1]{K_d} \text{EMHT}^{4-} \xrightleftharpoons[K_d]{K_d} \text{EMT}^{5-} + \text{H}^+$	
M^{3+}	$k_1 (\text{M}^{-1} \text{sec}^{-1})$
Dy^{3+}	2.2×10^5
Ho^{3+}	1.4×10^5
Er^{3+}	1.0×10^5
Y^{3+}	1.1×10^5
Yb^{3+}	4.0×10^4

25°C, ionic strength 0.1, and $K_d \geq 10^{-5}$

The rate constants of complexation reactions between rare earth ions and murexide, oxalic acid and anthranic acid were $10^7 \sim 10^8 \text{M}^{-1} \text{sec}^{-1}$, nearly independent of the incoming ligands. The values of k_1 which show the rate constants of complexation reactions between EDTA coordinated rare earth ions (EM^-) and HT^{3-} are about 2~3 order less than those of aquo complexes (M^{3+}) with murexide, etc.

Generally, complexation reactions proceed *via* the diffusion-controlled ion-pair formation. The rate-determining step is considered to be the release of water molecule from the inner coordinated sphere of rare earth ions¹⁾. On the complexation reaction of EM^- with HT^{3-} , coordinated EDTA prevents the ion-pair formation with HT^{3-} by steric hindrance and electrostatic repulsion. The decreased rate constant of rare earth-EDTA-tiron mixed complex formation reactions may be understood by these ligand-ligand repulsions.
